

Theorem 2. Suppose that X is a discrete random variable with the probability mass function $P(X = x_i) = p_i, i = 1, 2, \dots, r$ and support in the finite interval $[a, b]$. If $m(x)$ and $n(x)$ are both increasing (or decreasing) in $[a, b]$, then we have $m(X)$ dominates $n(X)$ by ε -AFSD if and only if

$$\sum_{i \in I} [n(x_i) - m(x_i)] p_i \leq \varepsilon \sum_{i=1}^r |n(x_i) - m(x_i)| p_i,$$

where $I = \{i \mid m(x_i) < n(x_i), 1 \leq i \leq r\}$.

Proof of Theorem 2. This proof is very similar to that of Theorem 1 and the concise proof is shown as follows.

Without loss of generality, we first assume that $x_1 < x_2 < \dots < x_r$.

(1) "If" part: Suppose $m(x)$ and $n(x)$ are both increasing in $[a, b]$. We only need to prove that if $\sum_{i \in I} [n(x_i) - m(x_i)] p_i > \varepsilon \sum_{i=1}^r |n(x_i) - m(x_i)| p_i$, then there exists a utility function $u(x) \in U_1^*(\varepsilon)$, such that $E[u(m(X))] - E[u(n(X))] < 0$.

For convenience, we suppose $I = \{s, s+1, \dots, t\}$. From the known conditions, we deduce that

- (i) $m(x_i) \geq n(x_i)$ if $i < s$;
- (ii) $m(x_i) < n(x_i)$ if $s \leq i \leq t$;
- (iii) $m(x_i) \geq n(x_i)$ if $i > t$.

Define

$$u(x) = \begin{cases} l_1 x, & x < m(x_s) \\ l_2 x - (l_2 - l_1) m(x_s), & m(x_s) \leq x \leq n(x_t) \\ l_1 x + (l_2 - l_1) [n(x_t) - m(x_s)], & x > n(x_t) \end{cases}$$

where $l_2 > l_1 > 0$ and $\frac{l_1}{l_1 + l_2} = \varepsilon$. It is obvious that $u(x) \in U_1^*(\varepsilon)$ and (i) for any $i < s$, we have $m(x_i) \leq m(x_s)$; (ii) for any $s \leq i \leq t$, we have $m(x_i) \geq m(x_s)$ and $m(x_i) < n(x_i) \leq n(x_t)$; (iii) for any $i > t$, we have $m(x_i) \geq n(x_i) \geq n(x_t)$. Hence, we get

$$u(m(x_i)) = \begin{cases} l_1 m(x_i), & i < s \\ l_2 m(x_i) - (l_2 - l_1) m(x_s), & s \leq i \leq t \\ l_1 m(x_i) + (l_2 - l_1) [n(x_t) - m(x_s)], & i > t \end{cases}$$

Similarly, we have

$$u(n(x_i)) = \begin{cases} l_1 n(x_i), & i < s \\ l_2 n(x_i) - (l_2 - l_1) m(x_s), & s \leq i \leq t \\ l_1 n(x_i) + (l_2 - l_1) [n(x_t) - m(x_s)], & i > t \end{cases}$$

Therefore, we obtain

$$u(m(x_i)) - u(n(x_i)) = \begin{cases} l_1[m(x_i) - n(x_i)], & i < s \\ l_2[m(x_i) - n(x_i)], & s \leq i \leq t \\ l_1[m(x_i) - n(x_i)], & i > t \end{cases}$$

and

$$\begin{aligned} E(u(m(X)) - E(u(n(X))) &= \sum_{i=1}^r [u(m(x_i)) - u(n(x_i))] p_i \\ &= l_1 \sum_{i=1}^{s-1} [m(x_i) - n(x_i)] p_i + l_2 \sum_{i=s}^t [m(x_i) - n(x_i)] p_i + l_1 \sum_{i=t+1}^r [m(x_i) - n(x_i)] p_i \\ &= l_1 \sum_{i=1}^r |m(x_i) - n(x_i)| p_i - (l_1 + l_2) \sum_{i=s}^t [n(x_i) - m(x_i)] p_i \\ &= (l_1 + l_2) \left\{ \varepsilon \sum_{i=1}^r |m(x_i) - n(x_i)| p_i - \sum_{i=s}^t [n(x_i) - m(x_i)] p_i \right\} \\ &< 0. \end{aligned}$$

Similarly, if $m(x)$ and $n(x)$ are both decreasing in $[a, b]$, we only need to redefine

$$u(x) = \begin{cases} l_1 x, & x < m(x_t) \\ l_2 x - (l_2 - l_1) m(x_t), & m(x_t) \leq x \leq n(x_s) \\ l_1 x + (l_2 - l_1) [n(x_s) - m(x_t)], & x > n(x_s) \end{cases}$$

where $l_2 > l_1 > 0$ and $\frac{l_1}{l_1 + l_2} = \varepsilon$. By repeating the above process, we can also deduce that

$$E(u(m(X)) - E(u(n(X))) < 0.$$

(2) “Only if” part: Suppose $\sum_{i \in I} [n(x_i) - m(x_i)] p_i \leq \varepsilon \sum_{i=1}^r |n(x_i) - m(x_i)| p_i$, then for any

$u(x) \in U_1^*(\varepsilon)$, if $\inf_{x \in [a, b]} u'(x) = l_1$ and $\sup_{x \in [a, b]} u'(x) = l_2$, we get $\varepsilon \leq \frac{l_1}{l_1 + l_2}$. Thus, we deduce that

$$\begin{aligned} E(u(m(X)) - E(u(n(X))) &= \sum_{i=1}^r [u(m(x_i)) - u(n(x_i))] p_i \\ &= \sum_{i=1}^r u'(\xi_{x_i}) [m(x_i) - n(x_i)] p_i \quad (\text{where } \xi_{x_i} \text{ is among } m(x_i) \text{ and } n(x_i)) \\ &= \sum_{i=1}^{s-1} u'(\xi_{x_i}) [m(x_i) - n(x_i)] p_i + \sum_{i=s}^t u'(\xi_{x_i}) [m(x_i) - n(x_i)] p_i + \sum_{i=t+1}^r u'(\xi_{x_i}) [m(x_i) - n(x_i)] p_i \\ &\geq l_1 \sum_{i=1}^{s-1} [m(x_i) - n(x_i)] p_i + l_2 \sum_{i=s}^t [m(x_i) - n(x_i)] p_i + l_1 \sum_{i=t+1}^r [m(x_i) - n(x_i)] p_i \\ &\geq l_1 \sum_{i=1}^r |m(x_i) - n(x_i)| p_i - (l_1 + l_2) \sum_{i=s}^t [n(x_i) - m(x_i)] p_i \\ &= (l_1 + l_2) \left(\varepsilon \sum_{i=1}^r |m(x_i) - n(x_i)| p_i - \sum_{i=s}^t [n(x_i) - m(x_i)] p_i \right) \\ &\geq 0. \square \end{aligned}$$
